Cryptography

Cryptosystem

A Cryptosystem is a 5-tuple (**P,K,C,E,D**)

A set **P** of plaintexts

A set K of keys

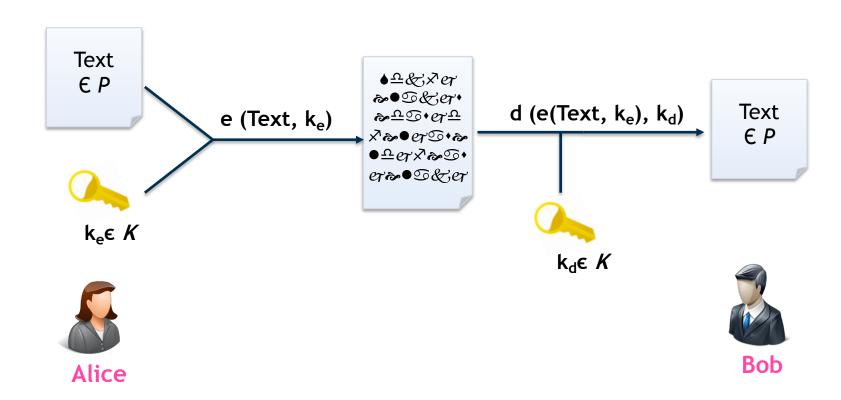

A set **C** of ciphertexts

A set *E* of enciphering functions, with *E: P x K -> C*

A set D of deciphering functions, with D: C x K -> P

Example

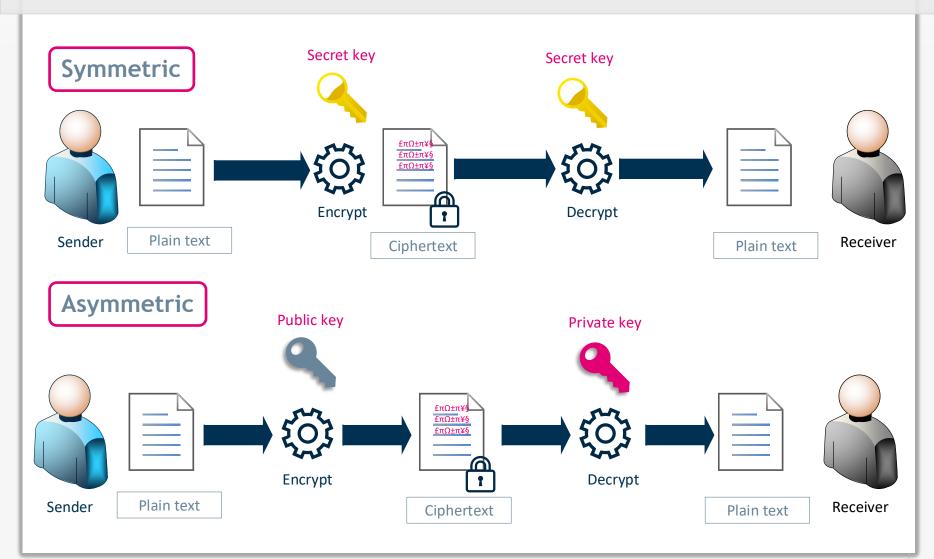

Cryptographic Systems (I)

- Intention
 - Confidentiality (secrecy of messages): encryption systems
 - Integrity (protection from undetected manipulation) and accountability: authentication systems and digital signature systems
- Key distribution
 - Symmetric: Both partners have the same key.
 - Asymmetric:
 Different (but related) keys for encryption and decryption

In practice mostly hybrid systems

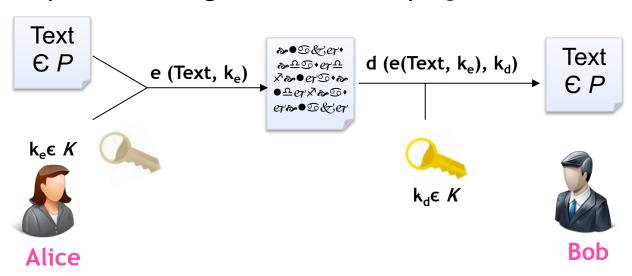

Cryptographic Systems (II)

Kerckhoffs' Principle

- The principle (first stated in 1883):
 - The secret lies within the key and not within the algorithm;
 - Thus "Security through obscurity" is not a sustainable solution.
- In our small example:
 - Separation of algorithm e and key k_e

Cryptography - Important Concepts

- Shannon's perfect secrecy
 - All plaintexts have the same probability for a given ciphertext.
- One-Time Pad Shannon / Vernam
 - Theoretically completely unbreakable, but highly impractical
- Shannon's concepts: Confusion and Diffusion
 - Relation between M, C, and K should be as complex as possible (M = message, C = cipher, K = key)
 - Every ciphertext character should depend on as many plaintext characters and as many characters of the encryption key as possible.
 - "Avalanche effect" (small modification, big impact)
- Trapdoor function (one-way function)
 - Fast in one direction, not in the opposite direction (without secret information)
 - Knowing the secret allows the function to work in the opposite direction (access to the trapdoor).

- In a ciphertext only attack, the adversary has only the ciphertext. Her goal is to find the corresponding plaintext. If possible, she may try to find the key, too.
- In a known plaintext attack, the adversary has the plaintext and the ciphertext that was enciphered. Her goal is to find the key that was used.
- In a *chosen plaintext* attack, the adversary may ask that specific plaintexts be enciphered. She is given the corresponding ciphertexts. Her goal is to find the key that was used.

Symmetric Key Cryptography

Symmetric Encryption Systems Applications & Examples

- Classical cryptosystems are usually based on symmetric encryption systems.
- Typical applications
 - confidential storage of user data
 - transfer of data between 2 users who negotiate a key via a secure channel
- Examples
 - Vernam-Code (one-time pad, Gilbert Vernam)
 - key length = length of the plaintext (information theoretically secure)
 - DES: Data Encryption Standard
 - key length 56 bit, so 2⁵⁶ different keys
 - AES: Advanced Encryption Standard (Rijndael, [NIST])
 - 3 alternatives for key length: 128, 192 und 256 bit

 - One time pad
 - AES
 - Advantages and Problems
- Public key cryptography

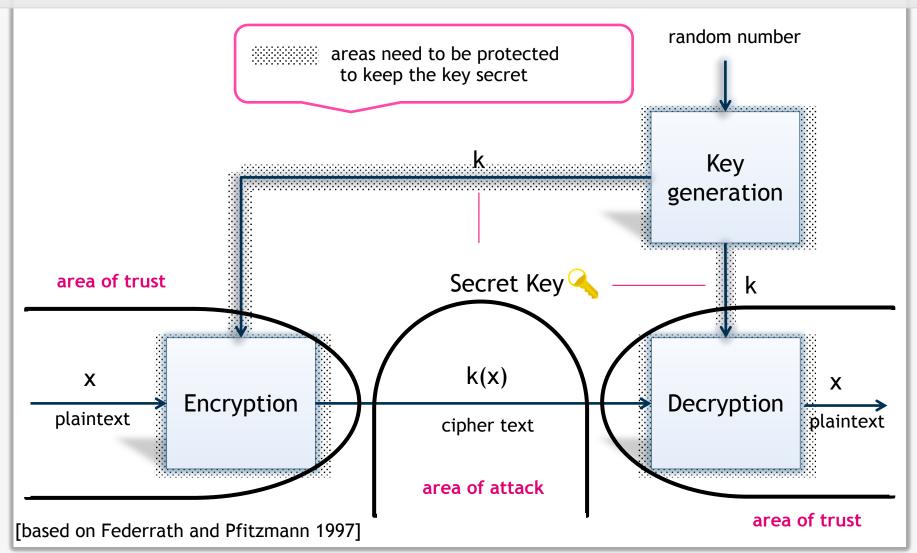

Symmetric Key Cryptography General Process

Symmetric Key Cryptography General Process

Symmetric Key Cryptography General Process

- Keys have to be kept secret (secret key crypto system).
- It must not be possible to infer on the plaintext or the keys used from the encrypted text (ideally encrypted text is not distinguishable from a numerical random sequence).
- Each key shall be equally probable.
- In principle each system with limited key length is breakable by testing all possible keys.
- Publication of encrypting and decrypting functions (algorithms) is considered as good style and is trustbuilding.
- Security of cryptosystems should base on the strength of chosen key lengths.

- Introduction
- Symmetric Key Cryptography
 - General process
 - Substitution ciphers
 - Caesar cipher
 - Vigenére cipher
 - One time pad
 - AES
 - Advantages and Problems
- Public key cryptography

Caesar Cipher

Α	В	C	D	E	F	G	Н	I	J	K	L	M
0	1	2	3	4	5	6	7	8	9	10	11	12
N	0	Р	Q	R	S	Т	U	V	W	Χ	Υ	Z

- We assign a number for every character.
- This enables us to calculate with letters as if they were numbers.

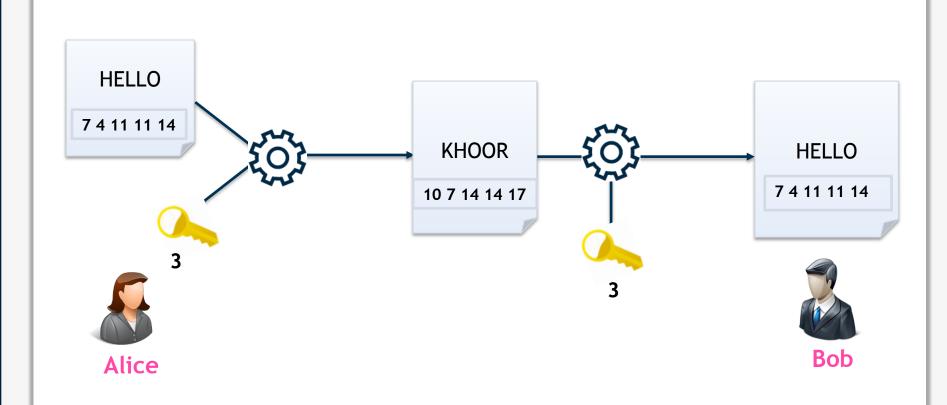

Caesar Cipher

- For k ε {0...25} we have:
 - An encryption function:
 - e: x -> (x+k) mod 26
 - A decryption function:
 - d: x -> (x-k) mod 26
 - In this case k_e = k_d

Example

Some Attacks

- In case of a known plaintext attack it is trivial to get the key used.
- There are only 26 possible keys. This cipher is therefore vulnerable to a brute force attack.
- This cipher is also vulnerable to a statistical ciphertext-only attack.

Assessment of Caesar Cipher

- Of course this is a very simple form of encryption.
- The encryption and decryption algorithms are very easy and fast to compute.
- It uses a very limited key space (n=26).
- Therefore, the encryption is very easy and fast to compromise.

Can We Make it More Secure?

- Use a permutation of the alphabet as the key.
- Example:

"HELLO" -> "ITSSG"

- Use of permutations increases the key space.
- Therefore, a brute force attack becomes more difficult.
- The encryption and decryption are not much harder to compute.
 - Table lookup
- Still vulnerable to a statistical ciphertextonly attack.

Statistical Ciphertext-only Attack

- Use statistical frequency of occurrence of single characters to figure out the key.
- Language dependent
- Frequencies of character pairs (bigrams) may also be used

E	11.1607%	M	3.0129%
A	8.4966%	Н	3.0034%
R	7.5809%	G	2.4705%
I	7.5448%	В	2.0720%
O	7.1635%	F	1.8121%
T	6.9509%	Υ	1.7779%
N	6.6544%	W	1.2899%
S	5.7351%	K	1.1016%
L	5.4893%	٧	1.0074%
C	4.5388%	X	0.2902%

- Introduction
- Symmetric Key-Cryptography
 - General process
 - Substitution ciphers
 - Caesar cipher
 - Vigenére cipher
 - One time pad
 - AES
 - Advantages and Problems
- Public key cryptography

Vigenére Cipher

- The Vigenére cipher chooses a sequence of keys, represented by a string.
- The key letters are applied to successive plaintext characters.
- When the end of the key is reached, the key starts over.
- The length of the key is called the period of the cipher.

Vigenére Tableau

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z ZZABCDEFGHIJKLMNOPQRSTUVWXY

Example

- Let the message be "THE BOY HAS THE BAG"
- and let the KEY be "VIG".

PT=T H E B O Y H A S T H E B A G

K= V I G V I G V I G V I G V I G

CT=O P K W W E C I Y O P K W I M

Assessment Vigenére Cipher

- For many years, the Vigenére cipher was considered unbreakable.
- Then a Prussian cavalry" officer named Kasiski noticed that repetitions occur when characters of the key appear over the same characters in the plaintext.
- The number of characters between successive repetitions is a multiple of the period (key length).
- Given this information and a short period the Vigenére cipher is quite easily breakable.
- Example: The Caesar cipher is a Vigenére cipher with a period of 1.

Example Vigenére Cipher

Let the message be "THE BOY HAS THE BAG" and let the key be "VIG":

• Plaintext:

Key:

Additional Example Vigenére Cipher

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z D E F G H I J K L M N O P Q R S T U V W J K L M N O P O R S T U V W X Y Z A B C D E F K L M N O P Q R S T U V W X Y Z A B C D E F G H I V W X Y Z A B C D E F G H I J K L M N O P Q R S T YZABCDEFGHIJKLMNOPQRS X X Y Z A B C D E F G H I J K L M N O P Q R S T U V W Y Y Z A B C D E F G H I J K L M N O P Q R S T U V W X ZZABCDEFGHIJKLMNOPQRSTUVWXY

Example

- Let the message be "HELLO"
- and let the KEY be "SEC"
- a=ZINLO
- b=ZINDS
- c=ZENNO

- Introduction
- Symmetric Key Cryptography
 - General process
 - Substitution ciphers
 - Caesar cipher
 - Vigenére cipher
 - One time pad
 - AES
 - Advantages and Problems
- Public key cryptography

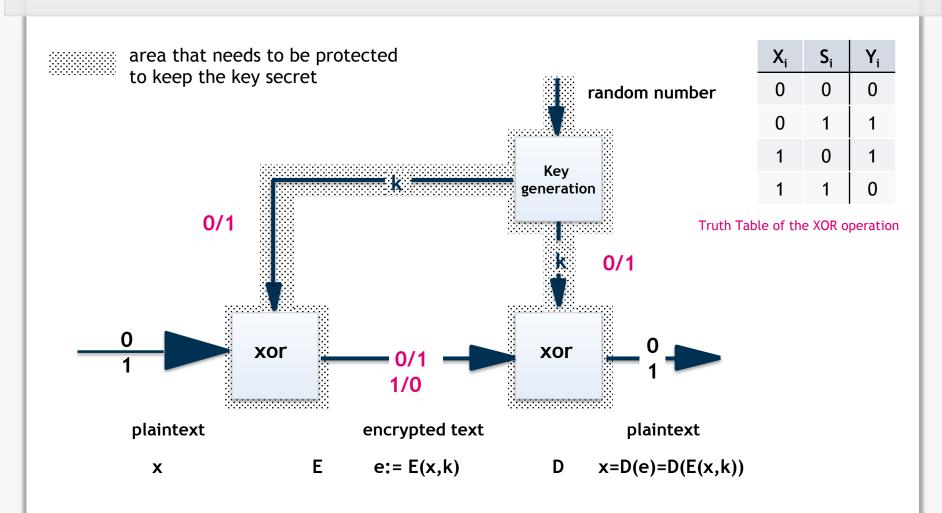

One Time Pad

- Invented by Gilbert Vernam
- The one-time pad is basically a Vigenére cipher.
- The length of the key is as long as the length of the plaintext.
- Therefore, there are no periodic reoccurrences.
- The key is randomly chosen and only used once.
- Every key has the same probability.

[based on Federrath and Pfitzmann 1997]

Example One Time Pad

35

Example

PT=	0	1	1	0
k=	1	0	1	1

X _i	S_{i}	Y_{i}
0	0	0
0	1	1
1	0	1
1	1	0

Truth Table of the XOR operation

a=	1	1	1	1
b=	1	0	1	1
C=	1	1	0	1

Assessment One Time Pad

- The one time pad is unbreakable by ciphertext only attacks.
 - Example: Let the ciphertext be "FGHA" .
 - Since we know the key length is at least 4 and the probability of every possible key is equal, the plaintext can be any 4-letter word possible.
- In a known plaintext attack we can deduct the key.
 - Then we know which key was used to encrypt the message we already know.
 - But the next message is encrypted with a different key, because every key is only used once.
- The same applies to a chosen plaintext attack.
- The one-time pad is information theoretically secure and provably impossible to break.

 - One time pad
 - AES
 - Advantages and Problems
- Public key cryptography

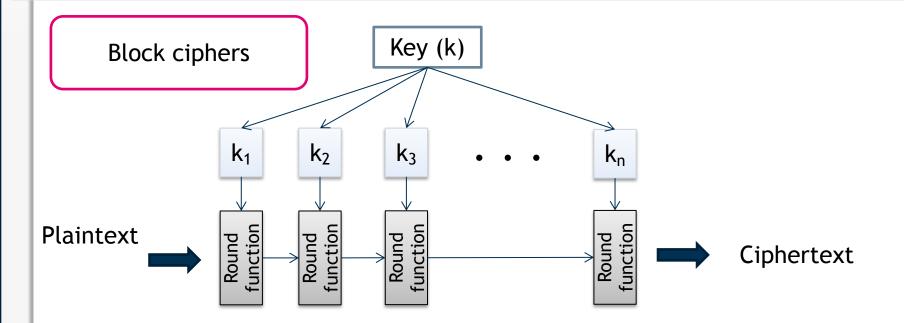

Advanced Encryption Standard (AES) - History

- The Data Encryption Standard (DES) was designed to encipher sensitive but not classified data.
- The standard has been issued in 1977.
- In 1998, a design for a computer system and software that could break any DES-enciphered message within a few days was published.
- By 1999, it was clear that the DES no longer provided the same level of security it had 10 years earlier, and the search was on for a new, stronger cipher.
- AES Rijndael was a winner of U.S. National Institute of Standards and Technology bid for advanced encryptions.
- AES has been approved for Secret or even Top Secret information by the NSA.

 [Bi05]

AES - Functionality

- Variable number of rounds (10, 12, 14)
- Depending on key size (128-bit, 192-bit, 256-bit).

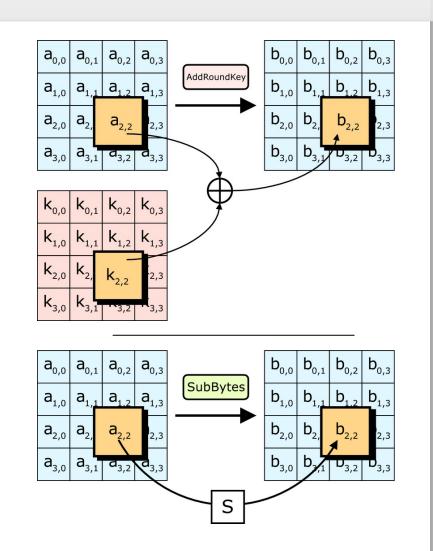

[Bi2005]

Encryption Round (1)

AES

- AddRoundKey
 - XOR (mix bits of) current state a and round key
 - Round key k derived using key schedule
- SubBytes
 - Substitution using a lookup table (S-Box)

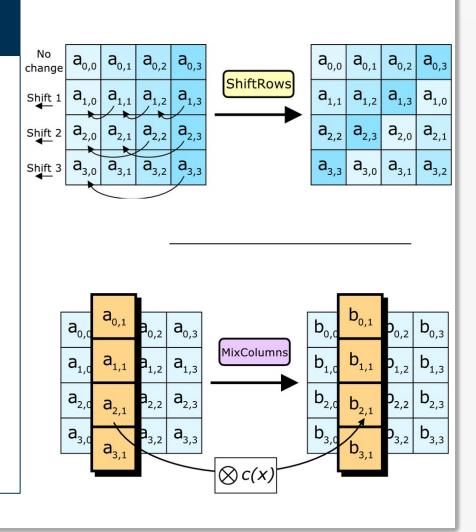

Encryption Round (2)

AES

- ShiftRows
 - Shift each row by row index
- MixColumns
 - 4 key bytes combined into each column using polynomial multiplication modulo 2⁸ [in GF(2⁸)]
 - GF = Galois field = finite field

Symmetric Encryption

Advantage: Algorithms are very fast

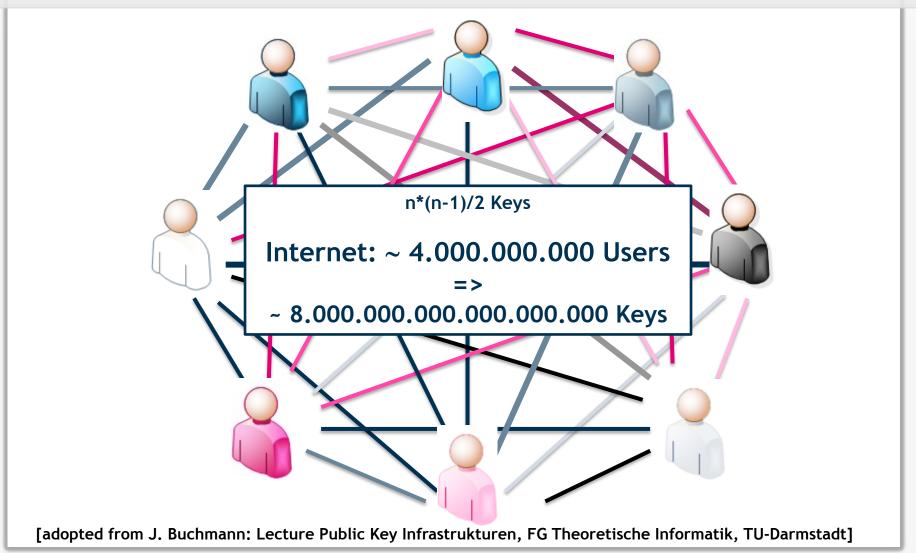

Algorithm	Performance*
RC6	78 ms
SERPENT	95 ms
IDEA	170 ms
MARS	80 ms
TWOFISH	100 ms
DES-ede	250 ms
RIJNDEAL (AES)	65 ms

^{*} Encryption of 1 MB on a Pentium 2.8 GHz, using the FlexiProvider Java)

[J. Buchmann: Lecture Public Key Infrastrukturen, FG Theoretische Informatik, TU-Darmstadt]

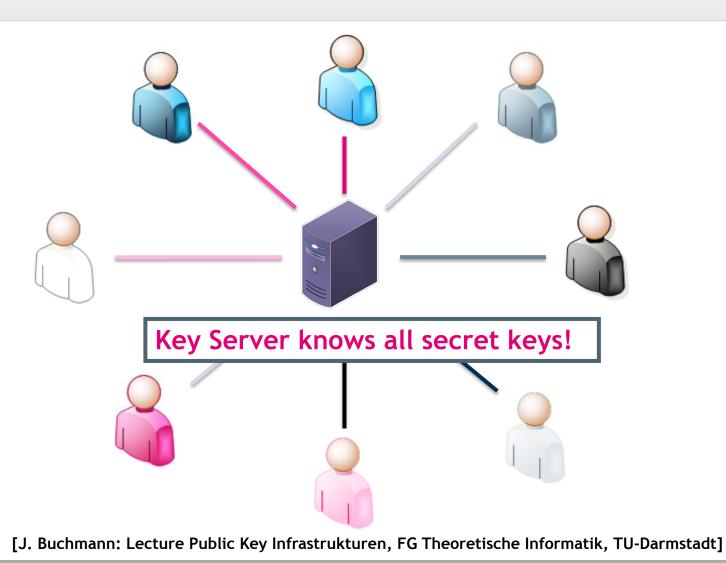

Disadvantage: Key Exchange

A Possible Solution

Key Management in Symmetric Encoding Systems

Key Distribution Center KDC

- One key per communication pair is necessary.
- Secure agreement and transfer are also challenging.
- A center for key distribution is possible but this party then knows all secret keys!

Secret key, encrypted for A k

Participant A

encrypted text

Participant B

Remark

Roger Needham / Butler Lampson

"Anybody who asserts that a problem is readily solved by encryption, understands neither encryption nor the problem."

[Marshall Symposium 1998] [Randell 2004]
